6.001--Another word of Introduction

If the automobile had followed the same development as the computer, a Rolls-Royce would today cost $100, get a million miles per gallon, and explode once a year killing everyone inside.

-- Robert Cringely, InfoWorld

Last lecture

- Basics of Scheme
  - Self-evaluating expressions
  - Names
  - Define
- Rules for evaluation

This lecture

- Adding procedures and procedural abstractions
- Using procedures to capture processes

Language elements -- abstractions

- Need to capture ways of doing things – use procedures

(lambda (x) (* x x))

•Special form – creates a procedure and returns it as value

Language elements -- abstractions

- Use this anywhere you would use a procedure

((lambda (x) (* x x)) 5)

Scheme Basics

- Rules for evaluation

1. If **self-evaluating,** return value.
2. If a **name,** return value associated with name in environment.
3. If a **special form,** do something special.
4. If a **combination,** then
   a. *Evaluate* all of the subexpressions of combination (in any order)
   b. *apply* the operator to the values of the operands (arguments) and return result

- Rules for application

1. If procedure is **primitive procedure,** just do it.
2. If procedure is a **compound procedure,** then: **evaluate** the body of the procedure with each formal parameter replaced by the corresponding actual argument value.

Language elements -- abstractions

- Use this anywhere you would use a procedure

((lambda (x) (* x x)) 5)

(* 5 5)

25

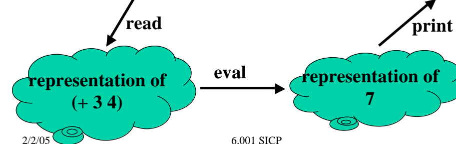
Can give it a name

(define square (lambda (x) (* x x)))
(square 5) → 25

Lambda: just what *is* a procedure?

```
(+ 3 4)                    expression
7                          printed representation of value
(lambda (x) (* x x))       expression
#[compound-procedure 9]    printed representation of value
```

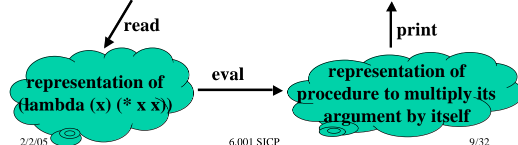
Remember the READ-EVAL-PRINT loop:



Lambda: just what *is* a procedure?

```
(+ 3 4)                    expression
7                          printed representation of value
(lambda (x) (* x x))       expression
#[compound-procedure 9]    printed representation of value
```

Remember the READ-EVAL-PRINT loop:



Interaction of define and lambda

```
1. (lambda (x) (* x x))
       ==> #[compound-procedure 9]
2. (define square (lambda (x) (* x x)))
       ==> undef
3. (square 4)                    ==> 16
4. ((lambda (x) (* x x)) 4)      ==> 16
5. (define (square x) (* x x)) ==> undef
```

This is a convenient shorthand (called "syntactic sugar") for 2 above – this is a use of lambda!

Lambda special form

- lambda syntax `(lambda (x y) (/ (+ x y) 2))`
- 1st operand position: the parameter list `(x y)`
  - a list of names (perhaps empty)
  - determines the number of operands required
- 2nd operand position: the body `(/ (+ x y) 2)`
  - may be any expression
  - not evaluated when the lambda is evaluated
  - evaluated when the procedure is applied
- semantics of lambda:

THE VALUE OF

A LAMBDA EXPRESSION

IS

A PROCEDURE

Corrolaries

- Any time you evaluate a lambda-expression, you create a procedure
- The only way to create a procedure is to evaluate a lambda-expression

Using procedures to describe processes

- How can we use the idea of a procedure to capture a computational process?

What does a procedure describe?

- Capturing a common pattern
  - (* 3 3)
  - (* 25 25)
  - (* foobar foobar)

```
(lambda (x) (* x x) )
```

Common pattern to capture

Name for thing that changes

Modularity of common patterns

Here is a common pattern:

```
(sqrt (+ (* 3 3) (* 4 4)))
(sqrt (+ (* 9 9) (* 16 16)))
(sqrt (+ (* 4 4) (* 4 4)))
```

Here is one way to capture this pattern:

```
(define pythagoras
  (lambda (x y)
    (sqrt (+ (* x x) (* y y)))))
```

Modularity of common patterns

Here is a common pattern:

```
(sqrt (+ (* 3 3) (* 4 4)))
(sqrt (+ (* 9 9) (* 16 16)))
(sqrt (+ (* 4 4) (* 4 4)))
```

But here is a cleaner way of capturing patterns:

```
(define square (lambda (x) (* x x)))
(define pythagoras
  (lambda (x y)
    (sqrt (+ (square x) (square y)))))
```

Why?

- Breaking computation into modules that capture commonality
  - Enables reuse in other places (e.g. square)
- Isolates details of computation within a procedure from use of the procedure
- May be many ways to divide up

```
(define square (lambda (x) (* x x)))
(define sum-squares
   (lambda (x y) (+ (square x) (square y))))
(define pythagoras
   (lambda (y x) (sqrt (sum-squares y x))))
```

Abstracting the process

- Stages in capturing common patterns of computation
  - Identify modules or stages of process
  - Capture each module within a procedural abstraction
  - Construct a procedure to control the interactions between the modules
  - Repeat the process within each module as necessary

A more complex example

- Remember our method for finding sqrts
  - To find the square root of X
    - Make a guess, called G
    - If G is close enough, stop
    - Else make a new guess by averaging G and X/G

The stages of “SQRT”

- When is something “close enough”
- How do we create a new guess
- How to we control the process of using the new guess in place of the old one

Procedural abstractions

For “close enough”:

```
(define close-enuf?
  (lambda (guess x)
    (< (abs (- (square guess) x)) 0.001)))
```

Note use of procedural abstraction!

Procedural abstractions

For “improve”:

```
(define average
    (lambda (a b) (/ (+ a b) 2)))
(define improve
    (lambda (guess x)
        (average guess
                 (/ x guess))))
```

Why this modularity?

- “Average” is something we are likely to want in other computations, so only need to create once
- Abstraction lets us separate implementation details from use
  - E.g. could redefine as

```
(define average
  (lambda (x y) (* (+ x y) 0.5)))
```

  - No other changes needed to procedures that use **average**
  - Also note that variables (or parameters) are internal to procedure – cannot be referred to by name outside of scope of lambda

Controlling the process

- Basic idea:
  - Given X, G, want `(improve G X)` as new guess
  - Need to make a decision – for this need a new *special form*

```
(if <predicate> <consequence> <alternative>)
```

2/2/05 6.001 SICP 25/32

The `IF` special form

```
(if <predicate> <consequent> <alternative>)
```

- Evaluator first evaluates the `<predicate>` expression.
- If it evaluates to a TRUE value, then the evaluator evaluates and returns the value of the `<consequent>` expression.
- Otherwise, it evaluates and returns the value of the `<alternative>` expression.
- **Why must this be a special form?**
  `(if (zero? x) 42 (/ 1.0 x))`

2/2/05 6.001 SICP 26/32

Controlling the process

- Basic idea:
  - Given X, G, want `(improve G X)` as new guess
  - Need to make a decision – for this need a new *special form*
  `(if <predicate> <consequence> <alternative>)`
  - So heart of process should be:

```
   (if (close-enuf? G X)
       G
                  (improve G X)          )
```

  - But somehow we want to use the value returned by "improving" things as the new guess, and repeat the process

2/2/05 6.001 SICP 27/32

Controlling the process

- Basic idea:
  - Given X, G, want `(improve G X)` as new guess
  - Need to make a decision – for this need a new *special form*
  `(if <predicate> <consequence> <alternative>)`
  - So heart of process should be:

```
(define sqrt-loop (lambda G X)
   (if (close-enuf? G X)
       G
       (sqrt-loop (improve G X) X       )
```

  - But somehow we want to use the value returned by "improving" things as the new guess, and repeat the process
  - Call process `sqrt-loop` and reuse it!

2/2/05 6.001 SICP 28/32

Putting it together

- Then we can create our procedure, by simply starting with some initial guess:

```
(define sqrt
    (lambda (x)
        (sqrt-loop 1.0 x)))
```

2/2/05 6.001 SICP 29/32

Checking that it does the "right thing"

- Next lecture, we will see a formal way of tracing evolution of evaluation process
- For now, just walk through basic steps
  - `(sqrt 2)`
    - `(sqrt-loop 1.0 2)`
    - `(if (close-enuf? 1.0 2) … …)`
    - `(sqrt-loop (improve 1.0 2) 2)`
    This is just like a normal combination
    - `(sqrt-loop 1.5 2)`
    - `(if (close-enuf? 1.5 2) … …)`
    - `(sqrt-loop 1.4166666 2)`
- And so on…

2/2/05 6.001 SICP 30/32

Abstracting the process

- Stages in capturing common patterns of computation
  - – Identify modules or stages of process
  - – Capture each module within a procedural abstraction
  - – Construct a procedure to control the interactions between the modules
  - – Repeat the process within each module as necessary

Summarizing Scheme

- Primitives
  - – Numbers **1, -2.5, 3.67e25**
  - – Strings
  - – Booleans
  - – Built in procedures ***, +, -, /, =, >, <,**
  - **-- Names**
- Means of Combination
  - – (procedure argument1 argument2 … argumentn)
- Means of Abstraction
  - – Lambda
  - – Define
- Other forms
  - – if

Creates a loop in system – allows abstraction of name for object

Enables means of combination

Create a procedure

Create names

Control order of evaluation
